15333 avenue of science: *Artificial Nucleases* Marina A. Zenkova, 2004-01-07 The development of agents capable of cleaving RNA and DNA has attracted considerable attention from researchers in the last few years, because of the immediate and very important applications they can find in the emerging fields of biotechnology and pharmacology. There are essentially two classes of these agents - nucleases that occur naturally inside cells and synthetically produced artificial nucleases. The first class includes protein enzyme nucleases and catalytic RNA structured ribozymes that perform cleavage of the phosphodiester bonds in nucleic acids according to a hydrolytic pathway in the course of different biochemical processes in the cell. A different pathway is used by some antibiotics which cleave DNA via redox-based mechanisms resulting in oxidative damage of nucleotide units and breakage of the DNA backbone. The above molecules are indispensable tools for manipulating nucleic acids and processing RNA; DNA-cleaving antibiotics and cytotoxic ribonucleases have demonstrated utility as chemotherapeutic agents. The second class, artificial nucleases, are rationally designed to imitate the active centers of natural enzymes by simple structures possessing minimal sets of the most important characteristics that are essential for catalysis. A different approach, in vitro selection, was also used to create artificial RNA and DNA enzymes capable of cleaving RNA. Being less efficient and specific as compared to the natural enzymes, the primitive mimics are smaller and robust and can function in a broad range of conditions.

Both the chemistry and design of positive and negative electrode materials are examined. In NIB, the electrolyte is also a crucial part of the batteries and the recent research, showing a possible alternative to classical electrolytes - with the development of ionic liquid-based electrolytes - is also explored. Cycling performance in NIB is also strongly associated with the quality of the electrode-electrolyte interface, where electrolyte degradation takes place; thus, Na-ion Batteries details the recent achievements in furthering knowledge of this interface. Finally, as the ultimate goal is commercialization of this new electrical storage technology, the last chapters are dedicated to the industrial point of view, given by two startup companies, who developed two different NIB chemistries for complementary applications and markets.

15333 avenue of science: Genetic and Genomic Resources of Grain Legume Improvement Mohar Singh, Hari D. Upadhyaya, I. S. Bisht, 2013-07-18 Grain legumes, including common-bean, chickpea, pigeonpea, pea, cowpea, lentil and others, form important constituents of global diets, both vegetarian and non-vegetarian. Despite this significant role, global production has increased only marginally in the past 50 years. The slow production growth, along with a rising human population and improved buying capacity has substantially reduced the per capita availability of food legumes. Changes in environmental climate have also had significant impact on production, creating a need to identify stable donors among genetic resources for environmentally robust genes and designing crops resilient to climate change. Genetic and Genomic Resources of Grain Legume Improvement is the first book to bring together the latest resources in plant genetics and genomics to facilitate the identification of specific germplasm, trait mapping and allele mining to more effectively develop biotic and abiotic-stress-resistant grains. This book will be an invaluable resource for researchers, crop biologists and students working with crop development. - Explores origin, distribution and diversity of grain legumes - Presents information on germplasm collection, evaluation and maintenance - Offers insight into pre-breeding/germplasm enhancement efforts - Integrates genomic and genetic resources in crop improvement - Internationally contributed work

15333 avenue of science: Progressive Myoclonus Epilepsies Berge A. Minassian, Pasquale Striano, Giuliano Avanzini, 2017 Progressive myoclonus epilepsies are a group of rare genetic diseases. The onset generally occurs around puberty in otherwise healthy children. They all involve

myoclonus and epilepsy but then differ depending on the different symptoms that are related. The outlook of these diseases is nearly always unfavourable and treatment only focuses on symptoms. Much planning will be needed to improve the quality of life for these children who will gradually become over time more and more severely disabled. Among these diseases, the most notable is Unverricht-Lundborg disease and Lafora disease, among others. However, the genetic mechanism of these diseases is simple and has been perfectly identified over time thanks to advancements in scientific discoveries. Hope lies in gene therapy, which in the near future will most likely be able to optimise treatment and even cure these children. This book addresses the situation by relying on clinicians descriptions, studies led by biologists on genetic variations and mutations and the work carried out daily by numerous scientists researching into treatment. By retracing the history of these diseases, from discovery and identification of mutated genes to the review of syndromes they encompass, this book marks the path we have travelled but also the distance we have yet to go.
